The Ecommerce AI Tools Guide: A Useful Repo for Ecommerce Sellers - and the App I Will Build Out of It

By Imtiaz Ahmad, Soft Tech Solution - a software developer and AI expert. I went through GitHub's new AI repos so sellers don't have to, and this is the one that is actually built for sellers, not developers. This guide is the blueprint on which I am working. It is written from the builder's side of the table: I design the systems; sellers run their businesses on them.

1. The Gap: A Listing With No Video, Keywords Guessed, and a Product AI Cannot Find

Most new AI repos on GitHub are built for developers. I went through them this week - coding agents, agent skills, phone harnesses - and almost all of them assume the reader writes code. The repo in this guide is the rare one that is built for the seller: nexscope-ai/ecommerce-ai-tools. I read the docs, compared the five video workflows, and checked the data directory before writing this.

The gap it closes is the listing itself. A seller's listing usually fails in three quiet places at once. First, the product has no video - a photo sits on the listing while every feed around it moves. Second, the keywords are guessed - the seller writes what they think buyers search, instead of checking what buyers actually search and say. Third, the product is invisible to AI - search engines and AI systems have no clean public page to read, so they cannot find it, quote it, or recommend it.

None of those three is a sales problem. They are listing problems, and they are all fixable with the same three tools - product videos, marketplace data, and a free public product page. That is what is inside this repo, and that is what this guide turns into an app.

2. The Custom App, Piece by Piece

The app I will build out of this repo is a custom dashboard for ecommerce sellers - one place where video, data and discovery live together, not three tabs. Here is what goes into it, piece by piece.

1. A video queue that turns every listing's photos into videos, batch by batch.

The repo's five video workflows - Image to Video, URL to Video, Avatar Video, Video Clone and Bulk Video - become one queue. The seller's product photos go in, videos come out: from a photo, from a listing link, with a presenter, from a reference clip, or a whole batch at once. The queue works through the listings one by one, so no listing is left as a photo while the rest move.

2. A keyword and review watch that tracks listings against real marketplace data.

The repo's data directory covers Amazon, TikTok, 1688, Shopify, Shopee and Walmart - product search, reviews, sourcing, keywords and marketplace research. The dashboard watches the seller's listings against that data: which keywords buyers actually use, what reviewers actually complain about, and where the listing's words disagree with the market's words.

3. A product page live for search and AI discovery.

The repo's Product Gallery gives every product a public page - facts, images, optional video, and the store link - built for search and AI discovery. The dashboard lists each product in the gallery, so AI systems can find and cite what the seller sells, and shoppers follow the link to the store to buy.

4. One dashboard, not three tabs.

Video, data and discovery in the same place. The seller opens one dashboard and sees: which listings have a video and which do not, which keywords need fixing, and which products are live in the gallery. The work is one queue, not three tools opened in three tabs and forgotten.

3. The Three Tools, With the Numbers

Tool one - product videos: five workflows

Workflow	Starts from
Image to Video	Your product photos
URL to Video	A listing link
Avatar Video	An avatar presenter for your product
Video Clone	A reference clip
Bulk Video	A whole batch of products at once

Compare the workflows and watch the official examples before you generate anything. The directory and the examples are free to browse; video generation uses credits, so check the estimate in the selected workspace before generating.

Tool two - marketplace data: six marketplaces, one directory

What the directory covers	Detail
Marketplaces	Amazon, TikTok, 1688, Shopify, Shopee, Walmart
Find the data for	Product search, reviews, sourcing, keywords, marketplace research
How to use it	Compare operations, inspect descriptions and recorded usage, read the official API documentation, test before you integrate
Rule	Find the data for the task before you build anything on it

Tool three - the free product page

What you get	Detail
The page	Product facts, images, optional video, and your store link on one public page
Built for	Search and AI discovery - so AI systems can find and cite your product
Cost	Submission, editorial review, approved listing and display are completely free - no payment, no store account connection

What you get	Detail
How it works	Share a public product URL or Amazon ASIN, accurate details and at least one clear image; save the private management link; the product stays offline until reviewed, approved and published

4. Why This Matters: Video, Keywords and Discovery Decide Whether a Listing Sells

A seller who treats the listing as a system makes different decisions in three places:

- **Video:** feeds move, photos sit still. A listing with a video says more in ten seconds than a gallery of photos - and the five workflows mean the seller does not need a camera crew, a presenter, or a video editor. A photo they already have is the starting material.
- **Keywords:** the words on a listing decide who finds it. A keyword guessed from the seller's side is a bet; a keyword checked against marketplace data is a fact. The review watch matters just as much - buyers tell you in reviews what is wrong with the listing, the product, or the price, and a seller who reads them fixes the listing before the next buyer reads the same complaint.
- **Discovery:** search engines and AI systems can only recommend what they can read. A product with no clean public page is invisible to them, however good it is. A free gallery page is the cheapest discoverability a seller will ever get - it costs nothing, and it is the page AI quotes when a buyer asks.

The pattern I see again and again in my client work: the businesses that struggle are not the ones with bad products. They are the ones whose listings never got the video, the keywords, or the public page - the three things buyers and AI both read before deciding.

5. Business Impact: What Changes When the Listing Gets All Three

There is no single number in this guide because the repo does not promise one - it promises three tools, free to browse, and the honest cost is stated in section 7. What changes is the shape of the work:

- **Every listing gets a video:** the video queue works through the catalogue batch by batch, so the shop stops being a wall of still photos while competitors' feeds move. One listing done properly beats ten half-done.
- **Keywords stop being guesses:** the keyword and review watch flags the listings whose words disagree with what buyers search and say. Fixing one listing's keywords is a small job; fixing them across the catalogue is the difference between being found and being missed.
- **Products become findable by AI:** every product listed in the gallery has a public page built for search and AI discovery. That page is a source AI systems can cite - and it costs the seller nothing.

An illustrative scenario (not a client result): a shop with 20 listings. Making one video per listing by hand is an afternoon of work per batch, so it never happens - the listings stay still. With the five workflows and the Bulk Video queue, the same 20 listings go through one queue: photos in, videos

out, one listing at a time, until the catalogue moves. The saving is not money. It is the work finally getting done.

6. Build Roadmap: How I Will Build It, Step by Step

This is the roadmap I am following as I build this app out of the repo. It uses vibe-coding tools, so the build is fast and the seller is involved at every step - no technical background needed on their side.

Step 1 - Write the prompt (the spec).

Start with a prompt template that describes the app in plain language: "A dashboard for an ecommerce seller that turns every listing's product photos into videos through five workflows (Image to Video, URL to Video, Avatar Video, Video Clone, Bulk Video), watches the seller's keywords and reviews against marketplace data for Amazon, TikTok, 1688, Shopify, Shopee and Walmart, and lists every product on a free public page built for search and AI discovery - video, data and discovery in one dashboard." Paste this into your chosen builder and refine the output. The prompt is the spec - the clearer it is, the closer the first version lands.

Step 2 - Pick the builder.

Build the front end and dashboard with one of the vibe-coding platforms:

- v0 - fastest for polished dashboards from a prompt.
- Lovable - strong for full apps with data views and user accounts.
- Bolt - good for a working prototype in a single session.
- Replit - best if you want the code, hosting, and database in one place.

Step 3 - Build the video queue first, then the keyword watch.

This is the architecture decision that makes the app workable: the video queue is the core, because a listing without a video is the most visible gap. Build the queue, the five workflows, and the per-listing video status first; then add the keyword and review watch on top. Never build both halves at once and hope they reconcile.

Step 4 - Connect the data.

Wire in the real numbers:

- **Marketplace data:** the ecommerce Data APIs for Amazon, TikTok, 1688, Shopify, Shopee and Walmart - product search, reviews, sourcing and keywords - see the API documentation and the API selection guide.
- **Product Gallery:** list the seller's products on the free public page, with facts, images, optional video and the store link.

Start with one data source (keywords and reviews for the seller's best-selling listing), verify the watch flags a real keyword gap, then add the rest of the catalogue.

Step 5 - Test the queue against real listings.

This is the feature that makes the app a working tool instead of a report: take three real listings - one with good photos, one with a single poor photo, one with no usable photo - and check the queue produces a video for the first, flags the second, and asks for a better photo for the third. Test it against real listings before trusting it on the whole catalogue.

Step 6 - Deploy it.

Ship the app on Vercel or Netlify - both deploy from a repository in minutes, both give the seller a live link they can open on their phone, and both scale from one user to a team without a rebuild.

Step 7 - Run it for one month beside the old method.

Keep the old way of handling listings (photos only, guessed keywords, no public page) running in parallel for the first month. At month end, compare: the dashboard's count of listings with video, keywords fixed, and products live in the gallery against the month before. If every listing has a video and a live gallery page, the old method retires. If one listing is still still, the gap is a missing step in the queue - find it, add it, and the system gets stronger.

7. The Honest Cost

- **Directories and guides:** free to browse - compare the workflows and the data operations before you spend anything.
- **Video generation:** uses credits - check the estimate in the selected workspace before generating.
- **API requests:** follow each operation's account, access and credit requirements.
- **Product Gallery:** completely free - submission, editorial review, approved listing and display, $0. No payment, no store account connection.

8. Checklist: Try It on One Listing

- [ ] Pick your best photo - open the video workflows, compare them, watch an example, make one video.
- [ ] Check your keywords and reviews in the data directory - find your platform and read what buyers actually say.
- [ ] List the product free in the gallery - submit it and get a public page built for search and AI.
- [ ] Then wire all three into one dashboard - video queue, keyword watch, gallery page, one place.
- [ ] Repeat for the next listing - one listing done properly beats ten half-done.

9. The Blueprint I Am Working From

This guide is the blueprint on which I am working as I am building the ecommerce AI tools dashboard: the prompt template, the video-queue-first architecture, the data-connection steps, and the dashboard layout, all in one place. Everything in it is written to be used, not just read - work through the checklist in section 8 against one of your own listings, and the listing stops being a photo with guessed keywords.
