The Account-Health App I Build That Stops One Bad Week From Freezing a TikTok Shop

The gap: your shop runs on a score you can't see moving

In July 2026, TikTok Shop replaced its old violation points system for U.S. sellers with the Account Health Rating (AHR): a score from 0 to 1,000, based on your shop's activity over the last 180 days. Every shop starts at 200 points.

Here is why that starting number is a trap:

- **Points come back slowly.** You earn 4 points for every 200 completed orders, capped at 20 points a week. A shop doing 50 orders a day earns about 7 points a week from orders alone.
- **Points leave fast.** Deductions for policy breaches and missed performance standards are sized by severity and frequency, and a single serious violation can cost 20 to 30 points.
- **From 15 October 2026, seller-fault cancellations got expensive.** If your seller-fault cancellation rate crosses TikTok's threshold, you can lose up to 25 AHR points, plus face order volume limits.
- **The milestones are brutal.** At 150, 100, or 50 points, your shop is blocked from creating new listings and enrolling in mega campaigns for 7, 14, or 28 days. At 0 points, the account may be permanently deactivated.
- **Fulfillment is the most common way to lose points.** TikTok expects regular orders to be dispatched within 2 business days, and a late dispatch rate above 10% triggers enforcement.

Put it together and one bad week does the damage: a cancellation spike (up to 25 points) plus one serious violation (20 to 30 points) takes a 200-point shop to around 150 - the first restriction tier - before the seller even realises the score moved. And every point gained or lost stays on the record for 180 days.

Most sellers check their score after the restriction lands. By then the damage is done.

The app I build: an Account-Health App that watches the score so you don't have to

This is a custom application built for a TikTok seller's own shop. The seller connects their shop account once, and the app reads their real AHR data - no manual entry, no screenshots, no guessing. Here is what it does, piece by piece:

1. Live AHR dashboard. Your current score, your distance from each milestone (150, 100, 50, 0), and the trend - whether the score is climbing or sliding, and why. One screen, checked in seconds.

2. Threshold alerts before the freeze. TikTok itself warns you 10 points before the next milestone. The app goes further: it alerts you on WhatsApp the moment your trajectory points at a milestone - for example, "You are 20 points from the 150 freeze zone, and cancellations are the reason." The warning arrives while you can still act, not after the listing block.

3. Violation breakdown, order by order. Every deduction explained: which violation, which order, how many points it cost. This is what turns a mystery score into a fixable problem - you learn whether the leak is cancellations, late dispatch, or listing policy, instead of guessing.

4. Cancellation and dispatch monitors. Two live gauges for the two most common point-losers:

seller-fault cancellation rate against TikTok's threshold, and late dispatch rate against the 10% enforcement line. A gauge turning amber is a warning to fix fulfillment today, not a deduction tomorrow.

5. Policy-quiz recovery path. When a violation lands, TikTok offers a policy quiz tied to that violation category, and passing it restores points. The app maps each active violation to its quiz, tracks which quizzes are done, and shows the score recovery each one is worth - so recovery becomes a checklist, not a hope.

6. Restriction countdown. If a milestone is crossed, the app shows exactly what is blocked (new listings, mega campaigns), for how many days (7, 14, or 28), and what the score must reach to get out. No more opening Seller Center every morning wondering if the block lifted.

Why this matters: the score is the shop

On TikTok Shop, the AHR is not a report card - it is the permission to grow. At 150 you cannot launch new products. At 100 you cannot run mega campaigns for two weeks. At 50 you are frozen for 28 days. At 0 the shop is gone, and reactivation is at TikTok's discretion.

And the asymmetry is the whole story: losing 50 points takes one bad week; earning 50 points back through orders alone takes 2,500 completed orders. At 50 orders a day, that is 50 days - and that assumes nothing else goes wrong in the meantime. The sellers who survive are not the ones who never get a violation. They are the ones who see it coming and fix fulfillment before the next deduction.

Business impact: what one bad week actually costs (illustrative math)

Take a shop doing 50 orders a day at a $25 average order value - $1,250 a day in sales.

- **Week one, the slide:** a cancellation spike costs up to 25 points and a serious violation costs around 25 more. Score: 200 -> ~150. Result: 7 days blocked from new listings and mega campaigns. The launch pipeline stops for a week while competitors keep launching.
- **The climb back:** recovering those 50 points through orders alone needs 2,500 completed orders - 50 days at 50 orders a day. Policy quizzes speed it up, but only if the seller knows which quiz maps to which violation.
- **The slide continues if nothing changes:** another bad week drops the shop toward 100 - 14 days of restrictions. Then 50 - 28 days. Then 0, where the shop itself is at stake.

The app does not sell more products. It protects the permission to sell at all - and the math says that permission is worth more than any single campaign.

How it is built: the step-by-step roadmap

1. **Connect the shop.** The seller connects their TikTok Shop account through TikTok's official Partner API, so the app reads real AHR, violation, order, cancellation, and dispatch data.

2. **Prompt the build.** A prompt template describes the dashboard, the gauges, the alert engine, and the recovery checklist - this is the blueprint the app is built from.

3. **Build the app.** The dashboard, violation breakdown, and monitors are built with a vibe-coding tool - v0, Lovable, Bolt, or Replit - with the AHR milestone logic (150 / 100 / 50 / 0) coded in as the alert

thresholds.

4. **Wire the alerts.** Threshold warnings go out on WhatsApp and email the moment a gauge turns amber or the trajectory points at a milestone.

5. **Add the recovery module.** Each violation category maps to its TikTok policy quiz, with completion tracking and projected score recovery.

6. **Deploy.** The app ships on Vercel or Netlify, and the seller opens one dashboard each morning instead of digging through Seller Center.

Checklist: is your shop protected?

- [ ] You know your current AHR score today, not last week.
- [ ] You know your distance from 150, 100, and 50.
- [ ] Your seller-fault cancellation rate is below TikTok's threshold.
- [ ] Your late dispatch rate is below 10%.
- [ ] Every active violation has a mapped policy quiz, and you know what each quiz is worth.
- [ ] Someone - or something - alerts you before a milestone, not after.

If you cannot tick all six, your shop is running on a score you are not watching.
